RADC-TR-77-170, Volume II (of two)  
Final Technical Report  
May 1977

MINIMAL BASIC SEMANOL (76) SPECIFICATION LISTING

TRW Defense and Space Systems Group

Approved for public release; distribution unlimited.

BEST AVAILABLE COPY

AD NO.   
DDC FILE COPY

ROME AIR DEVELOPMENT CENTER  
Air Force Systems Command  
Griffiss Air Force Base, New York 13441

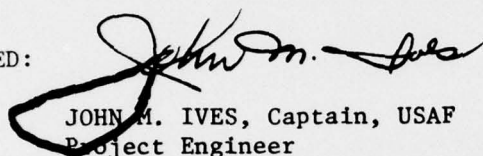

DDC  
RECEIVED  
JUN 28 1977  
D  

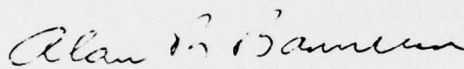

This report has been reviewed by the RADC Information Office (OI) and is releasable to the National Technical Information Service (NTIS). At NTIS it will be releasable to the general public, including foreign nations.

This report has been reviewed and is approved for publication.

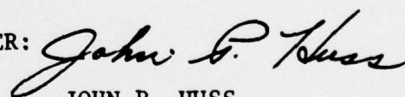

APPROVED:

  
JOHN M. IVES, Captain, USAF  
Project Engineer

APPROVED:

  
ALAN R. BARNUM  
Assistant Chief  
Information Sciences Division

FOR THE COMMANDER:

  
JOHN P. HUSS  
Acting Chief, Plans Office

Do not return this copy. Retain or destroy.

20. ABSTRACT (Continue on reverse side if necessary and identify by block number) This report contains a listing of the SEMANOL (76) metalanguage specification of the Minimal BASIC programming language. The specification is complete and has been extensively computer tested. The SEMANOL (76) metalanguage used here is a formal one that has an interpretive approach; its use has allowed implementation dependent semantics to be included in this specification.

"The BASIC standard prescribes certain actions for error conditions which can occur in the evaluation of the arithmetic operators. Overflow, division by zero and some special cases in involution are required to give a non-fatal error and return some standard result, possibly depending on one or both arguments. Underflow is not considered a non-fatal error, at least to the extent of listing it in the error section under the evaluation section. However, the remarks suggest that underflow be treated as an error, though clearly not requiring treatment as an error. We choose to model this by an implementation-dependent parameter whose value is #TRUE or #FALSE. If it is #TRUE, then underflow is uniformly treated as a non-fatal error, otherwise it returns the prescribed value, implementation-zero, with no other effect.

The BASIC standard specifies that non-fatal errors

=====

shall be reported and subjected to the specified error recovery procedures. The text of the report is implementation dependent. Generally, the recovery procedure returns some specified value. Usually it returns one of the implementation dependent limits, such as implementation-infinity or implementation-zero. For many cases, the standard specifies that either plus or minus infinity is the non-fatal recovery procedure result. The sign of the result is determined from the operands."

Conversions

=====

"In a number of places in the specification of BASIC, certain numbers are required to be integers, such as the TAB function or array bounds. To describe these things, it is convenient to convert the implementation numbers to semanol integers and operate on these integers. This can be accomplished in an implementation independent fashion by first converting the implementation dependent number to a canonical standard form number and then converting that to a SEMANOL integer."

#DF converted-to-semanol-integer(r)

=> significand-part(n) #CW (\$extrad-part(n)\$) zeros #.

"Define a conversion function to convert an  
implementation-number to a cononical form basic  
constant."

#DF converted-to-canonical-float (r)

"{ (\$r\$) is-implementation-number }"

=> ((\$r\$) converted-to-standard-float\$)  
in-canonical-form #.

"In order to define the proper output form of numbers, the implementor is required to define two parameters, the implementation-significance-width, also represented as the letter d, and the implementation-exrad-width, or e. The standard does not seem to require that d or e have any relation to the implementation precision or range. There is

=====

a requirement that  $d$  must be at least 6 and  $e$  must be at least 2. The resolved questions on page 35 are not part of the standard. It contains the only guideline for choosing  $d$  and  $e$ . The statement there is that the implementor may choose  $d$  and  $e$  to allow output of all numeric representations in the range of the implementation.

For the purpose of determining the output format for a given number, the class of possible numbers is divided into four classes.

- a. integers whose magnitude is in the range 0 to (but not including)  $10^d$ .
- b. non-integers whose magnitude is in the range  $0.1 - 0.5 \cdot 10^{-(d-1)}$  to (but not including)  $10^d - 0.5$ .
- c. Numbers less than  $0.1 - 0.5 \cdot 10^{-(d-1)}$  which can be represented exactly in  $d$  decimal digits.
- d. all other numbers.

This classification is derived from page 33, lines 1 thru 30. The possible formats are defined on page 13, lines 12 thru 15. Class a numbers are output using the so-called NR1 format. Class b use NR2. Class c also uses NR2 format by virtue of the fact that all its members can be exactly represented in the NR2 form. Note that for non-decimal implementations, numbers which are potentially in class c must be converted to decimal representation on a trial basis. Class d uses NR3 format.

The class b limits require some interpretation. We take it that the intent of class b is to describe those implementation numbers in the range of 0.1 upto  $10^d$ . The subtractive factors of one half and one half times  $10^{-(d-1)}$  would seem to represent the idea that the numbers to be included are those which can be rounded in the  $d+1$  th significant digit to produce a number in the range 0.1 to  $10^d$  with  $d$  or fewer significant digits.

The function to convert a number to output format is implementation independent. This is possible because the implementation number to be output is first converted to a BASIC constant. This BASIC constant can then be transformed to the appropriate output form using the standard arithmetic. Note that the following function converts the implementation number to a canonical basic constant. Subsequent functions are defined to operate on canonical numeric constants to simplify the definition."

"A standard arithmetic is defined as a standard of comparison for the implementation dependent arithmetic. The standard arithmetic was defined to operate on BASIC numeric-constants (see the CONTEXT-FREE-SYNTAX section). Defining arithmetic on the full range of BASIC numeric-constants is difficult. Therefore, a two step approach is used. In the first step( performed by the DF in-canonical-form), an arbitrary BASIC numeric-constant is transformed into another BASIC constant of a special form. The arithmetic operators then calculate their results from numbers in this canonical form. An examination of the standard-add DF shows how this two step process works in detail. The canonical form of BASIC numeric-constants are defined by the following grammar and equivalently by the DF is-canonical-float.

```
#DF canonical-numeric-constant
=> <#NILSET #U
<'-'>><standard-significand><'E'>
    <#NILSET #U <'-'>><standard-exrad> #.
#DF standard-significand
=> %1<'0'>
=> <%<#DIGIT>><#DIGIT #S- <'0'>> #.
#DF standard-exrad
=> %1<#DIGIT> #.
The value of the canonical constant aEb is
a*10^b."

=====

involves four sub-steps. These steps are tested and applied one at a time. The steps are:

1. Append a 'EO' to the constant if it does not already have an exrad.
2. Remove any leading plus signs in the exrad or significand.
3. Remove the decimal point from the significand. This may require adjusting the exrad to leave the value of the constant unchanged.
4. Remove any trailing zeros in the significand. Again, adjustment of the exrad may be necessary."

"Floating point division is the most complex of the floating  
point operations. Leaving aside some detail, the division  
result is the canonical result of dividing the dividend  
significand by the divisor significand to get the result  
significand and subtracting the divisor exrad from the  
dividend exrad to get the result exrad. Division by zero  
will result in #UNDEFINED being returned. The extra  
complication with division is the desire to specify the  
precision of the result. As an example suppose 1 is divided  
by 3 to a precision of 2 significant digits. The result  
should be 33E-2. To do this, the significand is multiplied  
by  $10^{(p-1+dl)}$  where p is the desired precision and dl is  
the length of the magnitude of the divisor. The exrad is

===== float-101 =====

changed to  $e - p + 1 - dl$ . This shifting is to guarantee that the result of the division will have at least  $p$  digits. The division is performed and the result is then realigned to have exactly  $p$  digits of precision. Then that result is canonicalized."

Specification of BASIC  
Semantic Definitions

01/28/77  
SEMANOL Project  
Arithmetic

=====

"In order for a specification of an implementation of BASIC to be complete, The implementor must define his implementation dependent number representation and the implementation dependent arithmetic operations upon those numbers. The following definition is meant to serve as a guide for other implementors. This definition was chosen to use the minimal parameters specified by the BASIC standard. In particular the base machine is considered to use decimal floating point numbers with six decimal digits in the significand and two decimal digits in the exrad. The range of the magnitude of legal values is 1F38 down to 1E-38 (inclusive at both boundaries).

It should be noted that only one implementation-precision is defined. It is assumed that the actual precision of the 'machine' is the same as the precision of the results of arithmetic operators and the result of converting a BASIC constant to an implementation-number."

"Define the legal form of an implementation number. For purposes of this sample implementation, we choose to use the floating point definitions defined by the standard representation and the operations defined upon that representation. However, we will modify this representation to require that the numbers have significands of no more than six digits. It is strongly recommended that the reader be familiar with the operation of the standard floating point functions."

#DF is-implementation-number(n)

```
=> #TRUE #IFF ($n$)is-canonical-float &
    #LENGTH(#ABS(significand-part(n))) <=
    implementation-precision & #NOT ($standard-abs(n)$)
    is-an-overflow & #NOT ($standard-abs(n)$)
    is-an-underflow #.
```

"For many parts of the basic specification, it is important to know if an implementation number represents an integer. Because an implementation number is a canonical number, it cannot have any trailing zeros in its significand.

"The definition of involution is very difficult. In order to handle the function, an external function is postulated which, for suitably restricted arguments, can return a result of more precision than implementation-precision. The external function will never return zero.

For the purposes of this example implementation, the domain of the involution function is split into several parts. This allows at least some test cases to involve the involution operator without involving the external function. With that in mind,  $0^x$  for any  $x$  is defined as 1.  $x^0$  for any  $x$  is also 1. Further,  $x^y$  for  $0 < y \leq \text{integer-exponentiation-limit}$  and  $y$  an integer is performed using multiplication."

"A set of implementation dependent relations is defined by BASIC. The implementation independent portion of the BASIC specification assumes that the implementation dependent relations will return a value in [#TRUE,#FALSE].

The BASIC standard is silent on the nature of the relations. In particular, It is assumed that no error conditions can occur in relational testing. If the testing is done using subtraction, this may not be the case since an overflow or underflow could occur. We choose to assume that this form of comparison is not legal and that no errors can occur."

# METRIC SYSTEM

## BASE UNITS:

Quantity	Unit	SI Symbol	Formula
length	metre	m	...
mass	kilogram	kg	...
time	second	s	...
electric current	ampere	A	...
thermodynamic temperature	kelvin	K	...
amount of substance	mole	mol	...
luminous intensity	candela	cd	...

## SUPPLEMENTARY UNITS:

plane angle	radian	rad	...
solid angle	steradian	sr	...

## DERIVED UNITS:

Acceleration	metre per second squared	...	m/s
activity (of a radioactive source)	disintegration per second	...	(disintegration)/s
angular acceleration	radian per second squared	...	rad/s
angular velocity	radian per second	...	rad/s
area	square metre	...	m
density	kilogram per cubic metre	...	kg/m
electric capacitance	farad	F	A·s/V
electrical conductance	siemens	S	A/V
electric field strength	volt per metre	...	V/m
electric inductance	henry	H	V·s/A
electric potential difference	volt	V	W/A
electric resistance	ohm	...	V/A
electromotive force	volt	V	W/A
energy	joule	J	N·m
entropy	joule per kelvin	...	J/K
force	newton	N	kg·m/s
frequency	hertz	Hz	(cycle)/s
illuminance	lux	lx	lm/m
luminance	candela per square metre	...	cd/m
luminous flux	lumen	lm	cd·sr
magnetic field strength	ampere per metre	...	A/m
magnetic flux	weber	Wb	V·s
magnetic flux density	tesla	T	Wb/m
magnetomotive force	ampere	A	...
power	watt	W	J/s
pressure	pascal	Pa	N/m
quantity of electricity	coulomb	C	A·s
quantity of heat	joule	J	N·m
radiant intensity	watt per steradian	...	W/sr
specific heat	joule per kilogram-kelvin	...	J/kg·K
stress	pascal	Pa	N/m
thermal conductivity	watt per metre-kelvin	...	W/m·K
velocity	metre per second	...	m/s
viscosity, dynamic	pascal-second	...	Pa·s
viscosity, kinematic	square metre per second	...	m/s
voltage	volt	V	W/A
volume	cubic metre	...	m
wavenumber	reciprocal metre	...	(wave)/m
work	joule	J	N·m
